Tin Shotti তিন সত্যি – a one-tap child mode for the parent's own phone

Abraar Masud Nafiz · Junior PM assessment, Nagorik Technologies · 4 Nov 2026 Key: [1] checked (sources at end) · ASSUMPTION not verified

In one line: when a parent hands their Android phone to a 3–8-year-old, Tin Shotti lets only the apps the parent picked open (YouTube Kids by default), shows the child how much time is left as a light round the screen edge, and ends the session kindly. Calls and 999 always work. Set up once in about 3 minutes, in Bangla. Diagrams, test cases, PRD and UI for each section: working notes.

1 Choose the problem [notes: problem framing, opportunity tree]

The situation. It is evening. A 3–8-year-old asks for Ammu's or Abbu's Android phone "to watch rhymes on YouTube". Autoplay pulls the child from learning videos to anything; getting the phone back ends in an argument; and the same phone holds the parent's WhatsApp and Facebook.

Why this first.

- One moment, the handover, holds three of the four comments: what the child watches next, the evening argument, and the setup that was too hard.
- The free tools fit it badly. Family Link needs the child signed in with their own Google Account[3]. YouTube Kids' approved-only mode and timer work only inside YouTube Kids[2]; app pinning keeps one app on screen[4]. Built-in kid modes exist, but each on one brand: Samsung Kids on Galaxy[10], realme's Kid Space (which locks the phone when time is up)[15]. Android 16's new Parental controls are set up for the child's own device[14].
- Children this young can't negotiate limits, so a rule the phone applies the same way every evening should help most. ASSUMPTION

9–14-year-olds: later, on purpose. Most have their own phone, where Family Link already fits[3]. If one shares a parent's phone, the same app works with a little more room: the parent can allow one or two more apps (a school or reading app). More options for older children come with v2.

One assumption that could make this wrong: most 3–8-year-olds watch on a parent's shared Android phone, not their own tablet or the TV. ASSUMPTION The landing page (section 4) asks every visitor which device their child uses most.

2 Define the MVP (one Android developer, six weeks) [notes: scope]

What it does	Why
1. One-tap handover with allowed apps. The parent taps *Give to child*. Only allowed apps open (YouTube Kids by default); any other app gets a friendly "grown-up app" cover. Grown-up apps can never be allowed; incoming calls and 999 always work[13].	Keeps "what they watch next" inside a safe app and the child out of WhatsApp and Facebook, without cutting off help. We don't filter videos: YouTube Kids does, free, in Bangladesh[1].
2. Daily time the child can see, and a kind ending. The parent sets daily minutes (optionally only 6–10 pm). A light grows round the screen edge as time runs out: no numbers, paused when the screen is off. Then a voice, confetti and "Well done"; extra time has a fixed limit (step 6).	The phone says "stop" the same way every evening, so there is less to argue about. Light and voice, not numbers: many 3–5-year-olds can't read. The core bet. ASSUMPTION
3. A 3-minute guided setup in Bangla. Pictures for the phone's brand (Xiaomi, Realme, Tecno, Samsung…) and a *Test it now* check. A forgotten PIN is reset with the phone's own screen lock.	Answers "setting it up was too difficult". The main thing the free route doesn't give.

Two things I would leave out. (1) **Our own content filtering**: YouTube Kids already filters, and one miss would destroy trust. (2) **A remote parent dashboard** (reports, location): it needs accounts, a backend and data about the child.

After the MVP: an all-day mode for a phone the child owns, and a safe browser. Both double the guard and privacy work, so the MVP proves the handover first (details in the notes).

Riskiest technical assumption. ASSUMPTION A normal Play Store app, without device-owner rights, can keep a child inside the allowed apps. What I could verify points the other way: without device-owner rights Android only offers screen pinning, which the user can leave[4], and battery savers on Xiaomi and Samsung often kill background apps[5].

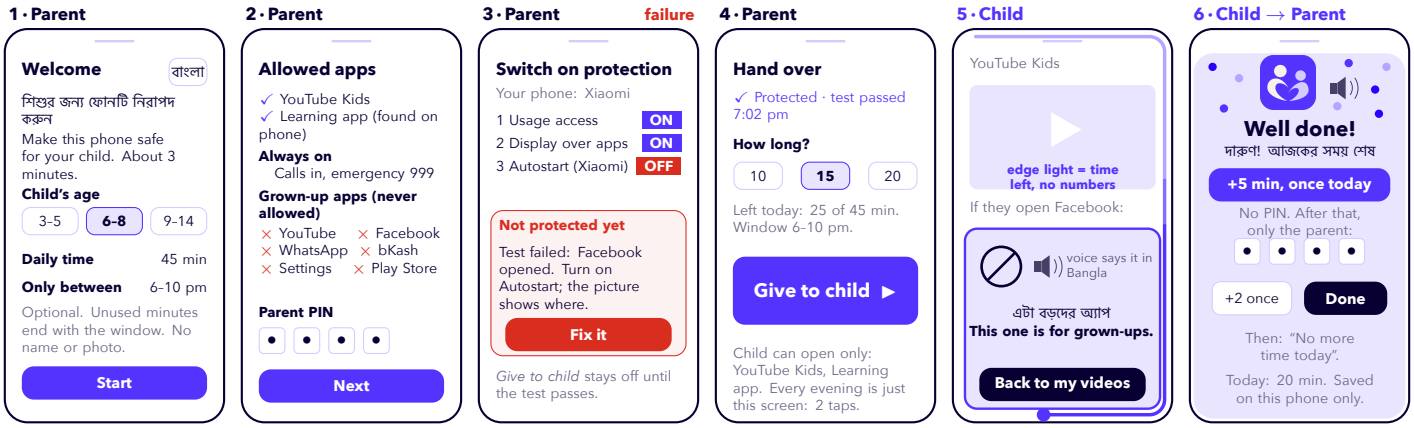

What I would ask the developer (a 3-day spike in week 1):

(a) On four low-cost phones (Android 10–15), *Usage access* + overlay vs an Accessibility service (Play declaration and consent[12]): is a blocked app covered within a second, does the guard last 45 min on battery saver, and do calls and 999 still work?
(b) Which escape routes would a 7-year-old find: notification shade, recent apps, split screen, a restart?
(c) What Play review needs (`isMonitoringTool`[8], foreground service, children's-app rules) and how long it takes.

Plan with one gate. Wk 1: spike and Figma prototype. Wk 2: payment test (section 4) while the developer builds setup and timer, needed in any version. **End of wk 2:** guard and test pass → build the guard (wks 3–4); guard fails → ship a guided setup of the free tools and re-test pricing; test fails → stop. Wk 3: an internal-test build goes to Play to clear the policy declarations early. Wk 5: closed test, 15 families. Wk 6: review and launch from Nagorik's organisation account, so the 14-day tester rule for new personal accounts[9] doesn't apply ASSUMPTION. AI coding speeds up screens, not testing on real phones. [notes: plan and gates]

3 Show the experience (steps 1–6 sketched at the top of page 2; Bangla first) [notes: journey map]

- **Parent does:** steps 1–4 once (about 3 minutes), then only step 4 each evening. **Child sees:** steps 5–6: only allowed apps, the time light, a voice and a kind ending.
- **Failure and how it's handled (step 3):** the battery saver kills the guard, or a permission is off. The app tests the guard before every handover; if it fails, the parent sees *Not protected yet* with the fix for their phone, and *Give to child* stays off. A guard that dies mid-session is a known limit: the parent is told at the next handover.
- **Privacy and trust decision:** Tin Shotti reads only *which app* is in front, never what is on screen or which videos play (a rule we declare to Play, even where Android would allow more). No child account, name or photo; session history stays on the phone, and only the counts in section 5 leave it. The child always sees the time light: open rules, not secret watching.
- **First useful result:** the first evening session that ends on time on the phone's word, not the parent's.

4 Explain why someone would pay [notes: competitor scan]

Why not the free option? Free tools exist and I would say so: YouTube Kids[2], app pinning[4], Digital Wellbeing app timers[11], brand kid modes (Samsung Kids[10], realme Kid Space[15]), and Android 16's Parental controls[14], which most low-cost phones here don't run yet ASSUMPTION. Google shipping more is the real risk, so speed and Bangla setup matter. A parent pays for what the free tools don't give on a shared phone:

1. **Setup they can finish:** one guided Bangla flow with steps for their phone's brand, instead of several settings menus (comment 3).
2. **The same thing on any Android brand:** YouTube Kids' limits work only inside YouTube Kids[2], pinning holds one app[4], app timers limit each app separately[11]; the kid modes work on one brand each, in their own menus[10,15]. We bet few parents find or use them. ASSUMPTION The landing page asks: "Have you used your phone's kid mode?"
3. **A calmer evening:** the same visible ending every day. ASSUMPTION until the week-5 closed test shows it. All-day mode (v2) could be a higher tier later.

Price: BDT 99 a month (about BDT 3 a day) after a 14-day free trial; under BDT 100 keeps it a small decision. ASSUMPTION **Paying is the second big risk.** Subscriptions must use Google Play billing[7], and Google's payment-methods page confirms only cards for Bangladesh[16]. Week 1: try bKash and operator billing on a Bangladeshi account. If neither works, sell through a telco or MFS bundle instead (Nagorik already works with both). ASSUMPTION

Test before building (week 2; BDT 5,000 of ads, about 500 visitors at BDT 10 a click ASSUMPTION): a Bangla landing page with a 40-second video of the version the spike says we can build, in parent Facebook groups and boosted in Dhaka and Chattogram. Every visitor first answers one tap: "Which device does your 3–8-year-old use most?" Then: "Reserve the founding price: pay BDT 99 by bKash, refunded on request or if we don't launch." It measures intent, not the Play payment route, so treat it as an upper bound.
Pass: 2% or more of visitors pay (about 10 of 500). **Reconsider if** under 0.5% pay, or most say "YouTube Kids or Samsung Kids is enough": make it free and earn another way (a telco or school bundle), or pick another problem. In between: retest the message, or BDT 49. 500 visitors only separate a clear yes from a clear no; the thresholds are guesses, set in advance.

5 Measure success

Outcome: week-2 return rate. Of the families who finish setup in launch week, the share who start at least 3 child sessions in week 2. Three evenings show the handover routine works for parent and child.
How: pseudonymous counts (setup finished; session started, with or without added time; session ended on time, after +5 or +2, early, or at the window's end) per random install ID, via Firebase Analytics with the advertising ID off, so no backend of our own. ASSUMPTION No child data, app names or video titles. Aim for 100+ setups from the reservation list and parent groups, plus 10 short calls.
Decision (set before launch): **40% or more: continue** and switch on the paywall; day-15 trial-to-paid is the next check (under 5%: back to section 4). **20–40%: change**: call 10 families who stopped; fix setup and phone-brand failures first. **Under 20%: stop** adding features and revisit the problem choice. **Guard on the core bet:** if on more than half of week-2 evenings the parent gives +2 or adds time in settings, the ending isn't working; that is "change", whatever the return rate. The child's own +5 is expected.

6 Also

Rejected alternative: our own "approved videos only" player on embedded YouTube. YouTube's API policies forbid charging users to watch embedded videos and blocking the player's links[6], and YouTube Kids already offers approved-only viewing, free.
Biggest unanswered question: does a timer the phone enforces reduce the evening argument, or does the child fight the phone after their +5, and the parent gives in every night? The week-5 closed test (15 families, a week each) and the +2 guard are set up to answer it.

I talked informally with a few parents I know; that is not research, so every claim about parents stays an assumption.

AI use: a Claude research agent gathered the sources; I checked each claim against its linked page, and the rest is marked ASSUMPTION. After informal talks with a few parents I made the calls on problem, cuts, price, thresholds and timer rules. Claude (via Claude Code) then drafted the PRD and diagrams from my sketches, drew the six screens, drafted the Bangla copy and the name shortlist, laid out this PDF and critiqued each draft; I kept what held up (missing free competitors, payment test before the build) and rejected the rest. The full workflow is in the notes.
